

METHOD OF OPTIMIZING THE TOPOLOGY OF THE IEEE 1394SERIAL BUS

BACKGROUND OF THE INVENTION

5 1. Field of the Invention

The present invention relates to the IEEE 1394 network, and more particularly a method of optimizing the topology of the IEEE 1394 serial bus.

2. Description of the Related Art

10 The IEEE 1394 is a multimedia interface of the next generation for enabling information exchange among various multimedia instruments according to the specification prepared by IEEE (Institute of Electrical and Electronics Engineers), which provides a serial bus standard to enable communication of audio and video data among multimedia instruments such as HD-TV, DVD and DVC, differing from the conventional interface only to allow the connection between the personal
15 ~~computer and the peripheral devices such as mouse, printer, scanner, etc. The IEEE~~ 1394 technology has been rapidly developed by engineers practicing electronics, communications and computer ^{technologies}, presently providing for a high data transmission speed of 400Mbps, ^a plug & play system, 63 nodes on a single bus, etc.

20 In order to optimize the topology of the IEEE 1394 serial bus ~~may be used~~ ^{may be used} the following three methods. First, the cable topology is reconstructed so as to

number of the ports and the transmission speed, connecting a non-used port of the node of the first priority with a port of the node of the second priority, and repeating the previous step until all of the nodes are connected together, whereby the nodes are connected through the ports according to priority order.

- 5 The present invention will now be described more specifically with reference to the drawings attached only by of example.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic diagram for illustrating the structure of the network of the IEEE 1394 serial bus employing three ports;

- 10 Fig. 2 is a flow chart for illustrating the procedure of optimizing the topology of the serial bus according to the present invention;

Figs. 3A to 3E illustrate an example of connecting the nodes according to the flow chart of Fig. 2; and

- 15 Figs. 4A to 4F illustrate another example of connecting the nodes according to the flow chart of Fig. 2.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

- Describing the procedure of optimizing the topology of the IEEE 1394 serial bus in connection with Fig. 3A, there are shown six nodes respectively providing
20 the transmission speeds (hereinafter referred to as "speed") of 100Mbps, 200Mbps and 400Mbps. Reference numerals 0, 1, 2 represent the port numbers of each node. Firstly, referring to Fig. 2, the bus controller detecting the number of the ports and

speed of each node in step 100. Then, the bus controller determines in step 110 whether the total port number is equal to or greater than $2(N-1)$, where "N" represents the number of all the nodes. This is to confirm that all the nodes may be connected with the serial bus. In the present embodiment, the number N of the nodes is 6, and the total port number 11, so that the prerequisite of the step 110 is satisfied. In step 130, the nodes are prioritized according to the speed and the number of ports. In this case, the speed is firstly considered, and then the number of ports. As shown in Fig. 3B, the order of priority becomes lower in the direction of the arrow from "A" to "B".

10 In step 140, a non-used port of the node of the first (higher) priority is connected with a port of the node of the second (lower) priority. Then, the bus controller sequentially repeats the steps 150, 160 and 140. Thus, the node of 400Mbps having three ports makes the first connection (①) with a node of 200Mbps having a single port as shown in Fig. 3C, and the second connection with
15 another node of 200Mbps having a single port as shown in Fig. 3D. Consequently, all the nodes are connected together as represented by the connections ①, ②, ③, ④, ⑤ in Fig. 3E. When it is confirmed in step 150 that all the nodes are completely connected, Fig. 3E shows the optimized topology map, where the maximum hop number HOP_{max} between two nodes has the minimum value (HOP_{max}
20 =3), and the speed capacity of each node is secured.

Describing another embodiment of optimizing the topology of the serial bus having six nodes as shown in Fig. 4A, the bus controller determines in step 110 whether the total port number is equal to or greater than $2(N-1)$. If the total port number is smaller than $2(N-1)$ indicating that the normal connection of the nodes
25 is impossible, the nodes are adjusted in step 120. In the present embodiment, the node number "N" is 6, and the total port number 11, so that the prerequisite of the

step 110 is satisfied. Then, the bus controller goes to step 130 to prioritize the nodes according to the speed and number of the ports, as shown in Fig. 4B. Likewise, the order of priority becomes lower in the direction of arrow from "A" to "B".

In step 140, a non-used port of the node of the first (higher) priority is
5 connected with a port of the node of the second (lower) priority. Thus, the node of 400Mbps having three ports makes the first connection (①) with the node of 400Mbps having a single port as shown in Fig. 4C. The bus controller sequentially repeats the steps 150, 160 and 140 to connect all the nodes. However, the nodes arranged as shown in Fig. 4A may not be normally connected through the steps 140
10 to 160. Namely, the fourth connection between a node of 200Mbps and a node of 100Mbps is impossible since each of 200Mbps nodes has a single port. More specifically describing in connection with Fig. 4D, the 200Mbps node may not be connected with the 100Mbps after making the first, second and third connections ①, ②, ③ between the nodes of 400Mbps and 200Mbps.

15 Hence, if the bus controller detects in step 160 that all ports of the node of higher priority are used, it goes to step 170 to separate the last connected node, and then to move the node of foremost priority among the next speed group before the separated node. Accordingly, the priority arrangement of the nodes as shown in Fig. 4B is rearranged as shown in Fig. 4E. Based on the new priority arrangement, the
20 bus controller repeats the steps 140 to 160 to achieve the final connections ①, ②, ③, ④, ⑤ as shown in Fig. 4F. Then, the bus controller goes to step 180 to determine whether the maximum hop number HOP_{max} exceeds 16. If so, the priority order is readjusted in step 190, returning to step 140. In the present embodiment, the maximum hop number HOP_{max} between two arbitrary nodes is 3, satisfying the
25 requirement of the step 180. Hence, in the optimized topology map as shown in Fig. 4E, the maximum hop number HOP_{max} between two nodes has the minimum value

($\text{HOP}_{\max}=3$), and the speed capacity of each node is secured.

While the present invention has been described with specific embodiments accompanied by the attached drawings, it will be appreciated by those skilled in the art that various changes and modifications may be made thereto without departing 5 the gist of the present invention.
